1. Introduction

- Kaggle¹ ...
- Meta-kaggle dataset [Risdal and Bozsolik \(2022\)](#).

1.1. Literature Review

This paper focuses on the two players innovation contest with a continuous time where the players' relative position is public information throughout the game. This is closely related to tug-of-war contest, which, to our knowledge, was first formally given by [Harris and Vickers \(1987\)](#) as a one-dimensional simplification of the multi-stage R&D race. The output processes are model by Brownian motions drifted with effort inputs, which is followed by [Budd et al. \(1993\)](#) who model the state of a dynamic competition of two innovative duopoly firms by a Brownian motion drifted by the effort gap, and solve the equilibrium approximately. Furthermore, [Moscarini and Smith \(2007\)](#) model the tug-of-war state as the gap of the two outputs directly, and draw an analytical equilibrium of the pure strategies.

2. The Model

We assume two players, i and j , compete for a prize $\theta > 0$ in a contest. Winner gets the prize and loser gets nothing. The contest starts at time zero. At every time $t \geq 0$, the representative player i chooses an effort level $q_{i,t}$ and burdens a quadratic cost $C_i(q_{i,t}) = c_i q_{i,t}^2/2$, with a lower c_i corresponding to higher ability. Denoted by y_t the *output gap* of player i and j at time t , driven by

$$dy_t = (q_{i,t} - q_{j,t})dt + \sigma dW_t \quad (1)$$

where W_t is a Brownian motion and $\sigma > 0$ measures the innovation risk.

We assume that the contest is equipped with a submission system that allows participants to upload their algorithms at any time and receive immediate feedback. For simplicity, we further assume that agents submit their intermediate results whenever they make progress. This setup enables the contest organizers to monitor all players' progress $x_{i,t}$ and $x_{j,t}$ in real time. This true output level, evaluated by the system, is only known by the game designer but not the two players.

At any time $t > 0$, the contest designer emits a *public* signal of the real output gap y_t . The signal is ambiguous and the game holder controls the ambiguity. The dynamic of signal is

$$dZ_t = y_t dt + \frac{dB_t}{\sqrt{\lambda}} \quad (2)$$

where B_t is standard Brownian motion independent with $(W_{i,t})$ and $(W_{j,t})$, and the parameter λ is set by the game holder to control the precision of signal. The larger the λ , the more accurate the signal would be.

The information set of both players at time $t \geq 0$ is $I_t \equiv \{Z_s : 0 \leq s \leq t\}$. Player i estimates the unknown output gap y_t based on the information set I_t . Let $\tilde{y}_t \equiv E(y_t | I_t)$ be the estimated output gap and $S_t \equiv E[(\tilde{y}_t - y_t)^2 | I_t]$ be the estimation variance. According to Chapter 1.2 of [Bensoussan \(1992\)](#), *Kalman-Bucy filter* gives the dynamics of \tilde{y}_t and S_t ,

$$d\tilde{y}_t = (q_{i,t} - q_{j,t})dt + \lambda S_t (dZ_t - \tilde{y}_t dt) \quad (3)$$

$$\frac{dS_t}{dt} = \sigma^2 - \lambda S_t^2 \quad (4)$$

Hence, the conditional distribution $y_t|I_t \sim \mathcal{N}(\tilde{y}_t, S_t|I_t)$ is fully captured by the mean \tilde{y}_t and variance S_t . If $\lambda = 0$, we have $S_t = S_0 + \sigma^2 t$, i.e., the estimation variance is increasing in time linearly. If $\lambda > 0$, the solution of (4) is

$$S_t = \begin{cases} \bar{S} \cdot \tanh \left\{ t \cdot \sigma \sqrt{\lambda} + \tanh^{-1} (S_0/\bar{S}) \right\} & \text{if } S_0 < \bar{S} \\ \bar{S} & \text{if } S_0 = \bar{S} \\ \bar{S} \cdot \coth \left\{ t \cdot \sigma \sqrt{\lambda} + \coth^{-1} (S_0/\bar{S}) \right\} & \text{if } S_0 > \bar{S} \end{cases} \quad (5)$$

Specifically, $\bar{S} = \sigma/\sqrt{\lambda}$ when $\lambda > 0$ and $\bar{S} = \infty$ when $\lambda = 0$. Please refer to Appendix A for the derivations. Figure 1 shows the evolution of S_t in time: estimation variance S_t converges to *steady state* \bar{S} as time goes by regardless of the starting estimation variance. For simplicity, we henceforth assume that $S_0 = \bar{S}$, hence $S_t \equiv \bar{S}$.

Figure 1 The evolution of S_t in time t , given that $\lambda = 1$ and $\sigma = 1$.

Following Ryvkin (2022), let's consider a dynamic contest with a fixed deadline. Suppose the contest is terminated when time $t = T > 0$. Since the steady state estimation variance \bar{S} is fixed as displayed above, the state of the game is fully characterized by a tuple (\tilde{y}_t, t) . At any time $0 \leq t < T$, player i optimizes her effort level $q_{i,\tau}$ in the remaining contest period $\tau \in [t, T)$ according to the following optimization problem,

$$V^i(\tilde{y}_t, t; q_{j,t}, \Theta_i) = \max_{\{q_{i,\tau}\}_{\tau=t}^T} \mathbb{E} \left(\theta \cdot 1_{\tilde{y}_T > 0} - \int_t^T C_i(q_{i,\tau}) d\tau \middle| I_t \right) \quad (6)$$

where $\Theta_i \equiv \{\theta, \lambda, \sigma, c_i\}$, subject to constraints (3), (4) and $q_{i,\tau} \geq 0$ for all $\tau \in [t, T)$. The optimization problem for player j is just symmetric to that of player i as $V^j(\tilde{y}_t, t) = V^i(-\tilde{y}_t, t)$. The corresponding Hamilton-Jacobi-Bellman (HJB) equation for player i is

$$0 = \max_{q_{i,t} \geq 0} \left[-\frac{c_i q_i^2}{2} + V_y^i \cdot (q_{i,t} - q_{j,t}) + V_t^i + \frac{V_{yy}^i}{2} \lambda \bar{S}^2 \right]$$

By definition, we have $\lambda \bar{S}^2 = \sigma^2$. Under the assumption of inner solution, we plug into the first order conditions $q_{i,t} = V_y^i / c_i$ and $q_{j,t} = -V_y^j / c_j$, we have the system of equations

$$\begin{aligned} \frac{1}{2c_i}(V_y^i)^2 + \frac{1}{c_j}V_y^i V_y^j + V_t^i + V_{yy}^i \frac{\sigma^2}{2} &= 0 \\ \frac{1}{2c_j}(V_y^j)^2 + \frac{1}{c_i}V_y^j V_y^i + V_t^j + V_{yy}^j \frac{\sigma^2}{2} &= 0 \end{aligned}$$

subject to boundary conditions $V^i(-\infty, t) = 0$, $V^i(+\infty, t) = \theta$, $V^j(-\infty, t) = \theta$, $V^j(+\infty, t) = 0$, $V^i(\tilde{y}_T, T) = \theta \cdot 1_{\tilde{y}_T > 0}$ and $V^j(\tilde{y}_T, T) = \theta \cdot 1_{\tilde{y}_T < 0}$.

The Nash equilibrium is summarized in the following lemma. We include a simplified version of the proof in the appendix:

LEMMA 1 (**Ryvkin 2022**). *In the Markov perfect equilibrium, the players' efforts in state $(y, t) \in \mathbb{R} \times [0, T)$ are given by*

$$m_{ij}(y, t) = \frac{e^{-z^2/2}}{\sqrt{2\pi\sigma^2(T-t)}} \cdot \frac{\sigma^2}{2} [\gamma(\rho_i) + \gamma(\rho_j)] [1 - \rho(z)^2] [1 \pm \rho(z)] \quad (7)$$

where $z = y/(\sigma\sqrt{T-t})$, $\rho(z) = \gamma^{-1}(\Phi(z) [\gamma(\rho_i) + \gamma(\rho_j)] - \gamma(\rho_j))$ and

$$\begin{aligned} \gamma(u) &= \frac{u}{1-u^2} + \frac{1}{2} \ln \frac{1+u}{1-u}, \quad u \in (-1, 1) \\ \rho_i &= \frac{e^{w_i} + e^{-w_j} - 2}{e^{w_i} - e^{-w_j}}, \quad \rho_j = \frac{e^{w_j} + e^{-w_i} - 2}{e^{w_j} - e^{-w_i}}, \quad w_{i(j)} = \frac{\theta}{\sigma^2 c_{i(j)}}. \end{aligned}$$

The variables $w_{i(j)}$ represent the abilities of two players, while $\rho_{i(j)}$ normalizes $w_{i(j)}$ into the interval $(-1, 1)$. It is not hard to see that $\gamma(\cdot)$ is strictly increasing on $(-1, 1)$, ranging from $-\infty$ to $+\infty$. Moreover, the equilibrium effort $m_{i(j)}$ can be represented to the product of $\phi(y; 0, \sigma^2(T-t))$, the probability density of normal distribution with mean zero and variance $\sigma^2(T-t)$ at the state y and an amplitude factor that only depends on the composite variable z .

Figure...

3. Model Estimation

In this section, we describe the estimation procedure. We first outline the data generation process, establishing the connection between the empirical data and the theoretical model discussed previously. Then, we introduce a structural estimation method using Bayesian framework.

3.1. Data Generating Process

For each contest on Kaggle, the observable information can be classified into three primary components:

The first component consists of essential contest details, including the contest duration, prize structure, information disclosure, and other governing rules. Contrary to the assumptions of our

model, a typical contest usually involves multiple teams rather than just two. We index the participating teams of the contest by $i \in \{1, 2, \dots, n\}$. To fully leverage the potential of the data and establish a connection with our theoretical model, let's assume that each participant perceives a competitor they are playing against at every moment, denoted as j . This perceived competitor is typically understood as the most prominent individual on the leaderboard, i.e., the person ranked first. When team i themselves hold the top position, their perceived competitor is the individual who poses the greatest threat, namely the person ranked second. Furthermore, the contests may feature intricate prize structures, such as the provision of multiple awards, rather than adhering to a winner-takes-all format. The issue will be discussed in Section 4.2.

The second component captures the submission events of each player i to the system, denoted by the sequence $\{\hat{t}_k^i\}_{k=1}^{N_i}$. Here, N_i represents for the total number of submissions by player i , and t represents for the time of each submission. We understand the submission events of player i and j as two conditional independent inhomogeneous Poisson processes, driven by the intensity functions $\tau_i(t)$ and $\tau_j(t)$.² Then, during any time interval \mathcal{S} of the contest duration \mathcal{T} , the Poisson arrival rate of submissions of the representative player i is given by $\int_{s \in \mathcal{S}} \tau_i(s) ds$. We assume the submission intensity $\tau_i(t)$ is proportional to the effort level $m_i(\tilde{y}_t, t)$. More specifically,

$$\tau_i(t) = r \cdot m_i(\tilde{y}_t, t) \quad (8)$$

where $r > 0$ is the common ratio of submission intensity and effort.

The third component of the observed data is an open leaderboard that records the real-time rankings and scores of each participant, denoted by \hat{x}_t^i . We interpret the difference in scores between i and j displayed on the leaderboard as the signal Z_t (defined in (2)) released by the contest organizer. Specifically, let's denote $\hat{y}_t = \hat{x}_t^i - \hat{x}_t^j$ the gap between displayed scores and

$$dZ_t = \hat{y}_t dt \quad (9)$$

As indicated in (2), we assume that \hat{y}_t represents a noisy signal, with its precision controlled by λ .

In practice, the leaderboard signals are inherently noisy, as organizers deliberately disclose only a subset of the full dataset to participants to mitigate the risk of overfitting. The proportion of the released data is generally known to all participants. In addition to the public leaderboard, most competitions hosted on Kaggle also maintain a private leaderboard, where organizers evaluate the true predictive performance of participants' models using the full dataset.

Beyond the uncertainty introduced by partial data disclosure, a second source of signal noise arises from the timing of leaderboard updates: rankings are refreshed only after model submissions,

² That is, given the intensity functions $\tau_i(t)$ and $\tau_j(t)$, the submission events $\{\hat{t}_k^i\}_{k=1}^{N_i}$ and $\{\hat{t}_k^j\}_{k=1}^{N_j}$ are mutually independent.

creating a delay relative to the true standings. It should be noted that such lag would bias our model estimates only if participants strategically timed their submissions. Although such strategic behaviour is theoretically possible, we abstract from it in this study. We assume that each submission follows a period of substantive effort, allowing the leaderboard rankings to broadly reflect the relative performance of algorithms based on the publicly available data.

3.2. Bayesian Framework

The likelihood function of any realization of this point process $\{t_k^i\}_{k=1}^{N_i}$ is given by

$$p\left(\{t_k^i\}_{k=1}^{N_i}|\tau_i\right) = \exp\left\{-\int_{s \in \mathcal{T}} \tau_i(s) ds\right\} \prod_{k=1}^{N_i} \tau_i(t_k^i) \quad (10)$$

By (3) and (9), the estimated gap \tilde{y}_t by the two players follows

$$d\tilde{y}_t = (q_{i,t} - q_{j,t})dt + \sqrt{\lambda}\sigma(\hat{y}_t - \tilde{y}_t)dt \quad (11)$$

Unknown parameters to be estimated:

- σ (Total innovation risk): prior
- c_i and c_j (Capacities)

3.3. Estimation Procedure

...

3.3.1. Discrete time. ...

4. Application

...

4.1. Synthetic Data

Before applying our estimation procedure to real-world contest data, we evaluate its potential on synthetically generated data.

Based on the following assumptions, we will next generate the submission data for two players in a data analysis competition:

- Total uncertainty: $\sigma = 5$
- Capacities: $c_i = 1.5$ and $c_j = 2$
- Contest duration: from 2025-01-01 to 2025-03-31
- Starting point $\tilde{y}_0 = 0$

Simulation algorithm:

4.2. Case Study

...

Algorithm 1 Synthetic Data Simulation

Input: $\{\hat{t}_k^i\}_{k=1}^{N_i}$, c_i , c_j , σ , r .

Initialize $\tilde{y}_t = 0$, $\hat{y}_t = 0$

for $t = 2025-01-01$ to $2025-03-31$ **do**

$m_i(\tilde{y}_t, t), m_j(\tilde{y}_t, t) \leftarrow (7)$

$\tilde{y}_{t+\Delta t} \leftarrow (11)$

end for

Output: (\tilde{y}_t) , (\hat{y}_t)

5. Conclusion

Appendix A: Solve S_t in Equation (4)

If S is in steady state $dS/dt = 0 \Leftrightarrow S = \bar{S} \equiv \sigma/\sqrt{\lambda}$. If S is not in steady state, i.e. $S \neq \bar{S}$, we first isolate the two variables and get

$$\frac{dS}{\sigma - \lambda S^2} = dt$$

Then, we take the integral on both sides

$$t = \int \frac{dS}{\sigma - \lambda S^2} = \frac{1}{\sigma\sqrt{\lambda}} \int \frac{dS\sqrt{\lambda}/\sigma}{1 - (S\sqrt{\lambda}/\sigma)^2} \equiv \frac{1}{\sigma\sqrt{\lambda}} \int \frac{du}{1 - u^2}$$

where $u = S\sqrt{\lambda}/\sigma = S/\bar{S}$. Hence,

$$\sigma\sqrt{\lambda} \cdot t = \begin{cases} \tanh^{-1}(u) - K_1, & \text{if } |u| < 1 \\ \coth^{-1}(u) - K_2, & \text{if } |u| > 1 \end{cases} = \begin{cases} \tanh^{-1}(S/\bar{S}) - K_1, & \text{if } S < \bar{S} \\ \coth^{-1}(S/\bar{S}) - K_2, & \text{if } S > \bar{S} \end{cases}$$

Thus, we conclude the non-steady state case that

$$S = \begin{cases} \bar{S} \cdot \tanh(\sigma\sqrt{\lambda} \cdot t + K_1), & \text{if } S < \bar{S} \\ \bar{S} \cdot \coth(\sigma\sqrt{\lambda} \cdot t + K_2), & \text{if } S > \bar{S} \end{cases}$$

Finally, we determine the constants K_1, K_2 by the initial condition S_0 and have

$$K_1 = \tanh^{-1}(S_0/\bar{S})$$

$$K_2 = \coth^{-1}(S_0/\bar{S})$$
